# Beckhoff Lightbus System Description

The Beckhoff Lightbus consists of an intelligent central module and a field bus based on fibre-optic conductor.

## Beckhoff Lightbus

The Beckhoff Lightbus is coupled to the host System via a DPRAM, thus guaranteeing fast and convenient communication.

Bus couplers for Beckhoff Bus terminals and diverse I/O modules are available for processing the process image. Modules and bus couplers are linked to one another in a ring structure. Thanks to the use of fibre-optic conductor, interference sensitivity is low and the data transfer rate of 2.5 Mbaud is high. Errors occurring in the fibre-optic ring are detected by the central module and are reported to the host system. Implemented ring diagnostics functions enable swift error detection and remedying.

A communication protocol optimized for speed and simplicity has been defined for data transfer between the central module and I/O modules. Below, this communication protocol is also referred to as a telegram.

Communication on the fibre-optic ring is controlled by the central module. It sends telegrams which pass through the individual modules and terminal rows in the fibre-optic ring, and which are ultimately received again and checked.

A telegram consists of the telegram frame and contents.

The telegram frame is required for serial, asynchronous data communication and consists of 1 start bit, 6 CRC check bits and 2 stop bits. The telegram frame is generated and checked by the hardware. Software support is not necessary.

The telegram contents are essentially based on a byte organization.

AD0 - AD7 constitute the so called address field. Up to 254 modules and terminal rows can be addressed via this address field (the addresses 0x00 and 0x0ff are reserved).

CR0 - CR3 defines the telegram type. The following functions can be defined in the telegram:

| CR3 | CR2 | CR1 | CR0 | Function                        | Description  |
|-----|-----|-----|-----|---------------------------------|--|
| 0   | 0   | 0   | 0   | READ                            | The addressed module inserts the input information in the data fields D0 - D3.   |
| 0   | 0   | 0   | 1   | READ/WRITE                      | The addressed module inserts the input information in the data fields D0 - D3 and accepts the output information.                  |
| 0   | 0   | 1   | 0   | ADDRESS INITIALIZATION          | The addressed module accepts the contents of D0 as the module address and sets D0 = 0.   |
| 0   | 0   | 1   | 1   | RAM                             | A special type of telegram for bus coupler BK2000  |
| 0   | 1   | 0   | 0   | ADDRESS CHECK AND COUNT COMMAND | Every module that is passed through increments the contents of D0 by 1. The addressed module transfers the contents from D0 to D3. |
| 1   | 0   | 0   | 1   | LOW INTENSITY COMMAND           | The addressed module reduces the send intensity by 20%.  |
| 1   | 0   | 1   | 1   | BROADCAST                       | A special type of telegram for bus coupler BK2000  |

The bytes D0 - D3 contain the actual user information. Processing of this user information data is defined by the control field.

The last byte in the telegram contains 2 reserve bits and 6 bits for generation of a CRC checksum. A Hamming distance of d=3 is achieved with a length of the contents amounting to 50 bits.

The Beckhoff Lightbus consists of a physical ring which can be split into 8 logical rings for processing the process image. A logical ring only operates on selected modules and terminal rows that are defined by means of so called Communication Description Lists (CDLs). Transfer of the CDLs from the host system to the central module will be discussed in further detail later.

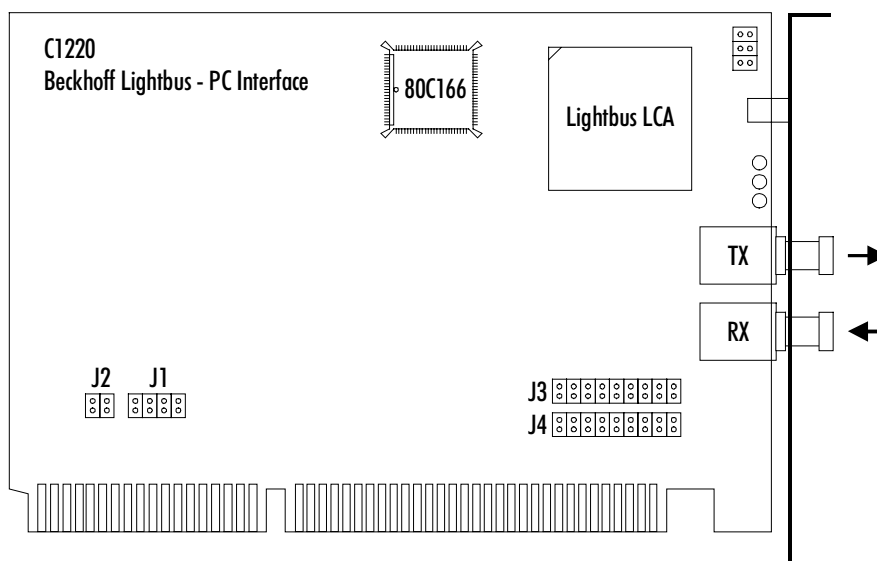

The process image is made available to the host system via the DPRAM. The DPRAM is split into three areas:-

- Data: Input, output and flags
- Communication: Initialization, test, analysis and configuration of the Beckhoff Lightbus
- Process control: Updating of process images

To this end, the central module requires a 4 k byte area in the address space of the host system.

# Hardware description of functions

*Lightbus PC interface card*  
C1220

The Lightbus - PC interface C1220 is an intelligent Lightbus central module.

*PC control*

As a plug-in ISA bus PC board, the C1220 links the Beckhoff Lightbus to the PC as the host system and is therefore an important component of the PC control concept.

With the aid of the C1220, fast processing of a process image defined by the sensors / actuators of the Beckhoff Lightbus is enabled.

# Software description of functions

## General

*Memory breakdown of the interface*

| Address area           | Function   |
|------------------------|--|
| <b>0x0000 - 0x0BFF</b> | Data area<br>(Inputs, outputs, flags)<br>3 kbytes                  |
| <b>0x0C00 - 0x0CFF</b> | Handshake channel 0: PC -> C1220<br>(configuration, test, analyse) |
| <b>0x0D00 - 0x0DFF</b> | Handshake channel 1: C1220 -> PC<br>(configuration, test, analyse) |
| <b>0x0E00 - 0x0FEF</b> | reserved   |
| <b>0x0FF0 - 0x0FFF</b> | GCB (General control block)  |

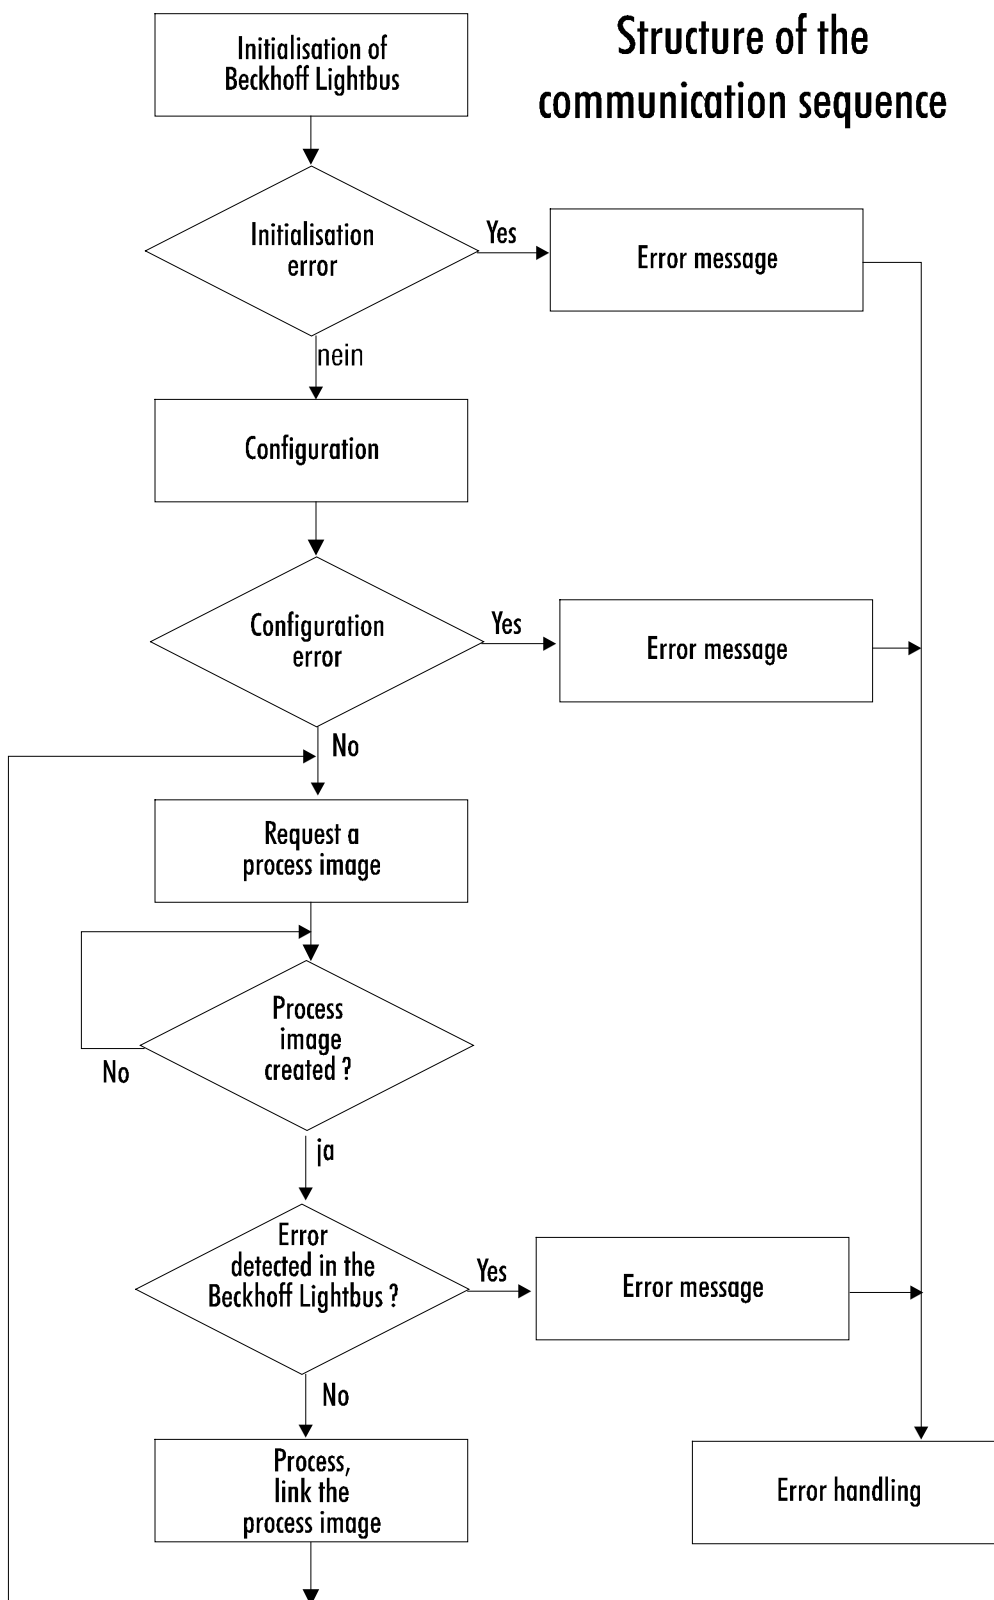

The interface between the PC bus and the C1220 module enables the following functions:

- Data transfer of the process image
- Test and analysis functions for the I/O system
- Configuration
- Control of process images

By way of the communication channels, the Beckhoff Lightbus can be configured by means of four functions. In doing so, the inputs / outputs of the decentralized I/O modules are assigned to the addresses in the DPRAM. A total of nine further functions can also be requested via the communication channels for test and analysis functions.

The data areas for the CDLs are located in the bottom 3 kbyte area that the C1220 module occupies in the address space. The request to update the process image is realized by setting a bit in the request mask of the GCB (General Control Block). The ready message for this request is obtained from the corresponding bit in the ready mask of the GCB.

### Structure of the communication sequence

## Description of the communication channels

Two channels are configured for communication between the PC bus and C1220. Each channel embraces 255 bytes. The PC writes the data required for requesting the required function into the channel 0 and then outputs a DV (Data Valid). After acceptance of the data, the C1220 module outputs the 'Quit' signal. The PC withdraws the 'DV' and a new communication can be commenced as soon as the 'Quit' signal is 0.

Channel 0 from the PC bus to the C1220 provides the address area from 0xC01 to 0xCFF for the data. DV is the MSB of the address 0xC00. 'Quit' is the second highest bit of the address 0xD00.

Communication channel 0:

|                 |        |       |          |                   |
|-----------------|--------|-------|----------|-------------------|
| Byte 0<br>0xC00 | Byte 1 | ..... | Byte 254 | Byte 255<br>0xCFF |
|                 |        |       |          |                   |

Channel 1 from the C1220 module to the PC bus provides the address area from 0xD01 to 0xDFF for the data. DV is the MSB of the address 0xD00. 'Quit' is the second highest bit of the address 0xC00.

Communication channel 1:

|                 |        |       |          |                   |
|-----------------|--------|-------|----------|-------------------|
| Byte 0<br>0xD00 | Byte 1 | ..... | Byte 254 | Byte 255<br>0xDFF |
|                 |        |       |          |                   |

Addresses of the  
Komunikationskanäle

| Address | Address bits |   |   |   |   |   |   |   | Contents   |
|---------|--------------|---|---|---|---|---|---|---|--|
|         | 7            | 6 | 5 | 4 | 3 | 2 | 1 | 0 |  |
| 0xC00   | 1            | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 'Data Valid' for Channel 0<br>(in the case of PC -> C1220 data transfer) |
| 0xC00   | 0            | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 'Quit' for Channel 1<br>(in the case of C1220 -> PC data transfer)       |
| 0xC01   |              |   |   |   |   |   |   |   | Length (von 2 bis 0xFE)  |
| 0xC02   |              |   |   |   |   |   |   |   | Functionsnummer<br>(1 bis 0xFE)  |
| 0xC03   |              |   |   |   |   |   |   |   | Argument 0   |

| 0x02 | Query code word                            |
| 0x03 | Query software version                     |
| 0x04 | Query parity error                         |
| 0x05 | Attenuation test                           |
| 0x06 | Count modules                              |
| 0x07 | Address test                               |
| 0x08 | Continuous sending                         |
| 0x09 | Software RESET                             |
| 0x0a | Fracture point test                        |
| 0x0b | Transfer freely programmable communication |
| 0x0c | Reinitialize CDL management                |
| 0x0d | reserved                                   |
| 0x0e | reserved                                   |
| 0x0f | Interrupt mask                             |
| 0x10 | Transfer CDL configuration                 |
| 0x11 | reserved                                   |
| 0x12 | Cyclic communication                       |
| 0x13 | reserved                                   |
| 0x14 | Initialize string communication            |
| 0x15 | Log in string node ???                     |
| 0xff | Invalid function request                   |

A function request is composed of a length entry, a function number and the function arguments. The length entry refers to the number of following bytes:

**Byte 'Length' + Byte 'Function number' + Number of Bytes 'Argument 0' to 'Argument n'**

## Test and analysis functions

### Fibre-optic reset

The fibre-optic ring can be reinitialized by means of this function. Within the scope of initialization, the number of modules in the ring is defined, the module addresses are distributed and tested and the ring is checked with regard to its attenuation reserve. Any existing fracture point is also detected and located.

| Channel        | Length | Function | Argument |    |    | Comment   |
|----------------|--------|----------|----------|----|----|---|
|                |        |          | 0        | 1  | 2  |   |
| <b>Request</b> | 02     | 0x01     |          |    |    |   |
| <b>Reply</b>   | 05     | 0x01     | 00       | 00 | nn | Function correctly executed (nn modules in the fibre-optic ring)          |
|                | 05     | 0x01     | 01       | 01 | 00 | Maximum number of send repetitions exceeded                               |
|                | 05     | 0x01     | 01       | 02 | 00 | No address setting possible   |
|                | 05     | 0x01     | 0a       | 01 | nn | Fracture point before nn-th module before the receiver input of the C1220 |
|                | 05     | 0x01     | 0a       | 01 | ff | Fracture point cannot be located (Fracture point before receiver input)   |
|                | 05     | 0x01     | 07       | 01 | nn | Test addresses:<br>Address error (module nn)                              |
|                | 05     | 0x01     | 05       | 02 | 00 | Attenuation test:<br>Error with high intensity                            |
|                | 05     | 0x01     | 05       | 03 | nn | Attenuation test:<br>Switch error with low intensity (module nn)          |
|                | 05     | 0x01     | 05       | 04 | nn | Attenuation test:<br>Error with data pattern 1 (pattern 00)(module nn)    |
|                | 05     | 0x01     | 05       | 05 | nn | Attenuation test<br>Error with data pattern 2 (pattern FF) (module nn)    |
|                | 05     | 0x01     | 05       | 06 | nn | Attenuation test :<br>Error with data pattern 3 (pattern AA) (module nn)  |
|                | 05     | 0x01     | 05       | 07 | nn | Attenuation test :<br>Switch error with high intensity (module nn)        |

The number of modules in the ring is communicated if the ring is initialized without errors. If an error should have occurred, the error type (see table) and the module address where the error occurred are returned.

### Code word

The C1220 outputs the code word after every reset of communication channel 1. Here, this takes place without setting the Data Valid bit. The purpose of the code word is to inform the PC that the C1220 interface card is initialized and ready. The code word can also be queried at any time by way of the 0x02 function.

| Channel | Length | Function | Argument |    |   | Comment           |
|---------|--------|----------|----------|----|---|-------------------|
|         |        |          | 0        | 1  | 2 |                   |
| Request | 02     | 0x02     |          |    |   |                   |
| Reply   | 04     | 0x02     | fe       | af |   | Correct code word |

### Software version

The version of the EPROM firmware can be queried by way of the 0x03 function.

| Channel | Length | Function | Argument |    |   | Comment      |
|---------|--------|----------|----------|----|---|--------------|
|         |        |          | 0        | 1  | 2 |              |
| Request | 02     | 0x03     |          |    |   |              |
| Reply   | 04     | 0x03     | xx       | xx |   | Version xxxx |

### Evaluation of Parity Errors

If the peripheral modules are fitted with type 132 or BX415 (BK2000) SPROMs, it is possible to localise the sources of parity errors. The master card produces a "parity error counter" (8 bits wide) for every module present. This counter works without overflow. The counter can be read by means of function 04.

| Channel | Length | Function | Argument |    |     | Comment   |
|---------|--------|----------|----------|----|-----|---|
|         |        |          | 0        | .. | 128 |   |
| Request | 03     | 0x04     | 00       |    |     | Transmit counter for modules 0 - 127                              |
| Reply   | 130    | 0x04     | n        | .. | y   | Counter for modules 0 – 127<br>(0 = non-localisable parity error) |
| Request | 03     | 0x04     | 01       |    |     | Transmit counter for modules 128 -255                             |
| Reply   | 130    | 0x04     | n        | .. | y   | Counter for modules 128 -255                                      |
| Request | 03     | 0x04     | 02       |    |     | Reset counter   |
| Reply   | 02     | 0x04     |          |    |     | Counter reset   |

### Fibre-optic attenuation test

The attenuation reserve of the fibre-optic ring can be tested with this function. In this test, all leaks of the fibre-optic ring are partially operated with approximately 80% of the normal transmission intensity and extreme test telegrams. This test can be run for all modules or for only one selected module (see table). The C1220 can be tested separately via the module address 0.

The table shows the function requests and the possible acknowledgements.

| Channel | Length | Function | Argument |    |   | Comment   |
|---------|--------|----------|----------|----|---|---|
|         |        |          | 0        | 1  | 2 |   |
| Request | 04     | 0x05     | 00       | 00 |   | Test all modules                                  |
|         | 04     | 0x05     | 01       | nn |   | Test module nn                                    |
| Reply   | 04     | 0x05     | 00       | 00 |   | Ring has adequate attenuation reserve             |
|         | 04     | 0x05     | 02       | 00 |   | Error with high intensity                         |
|         | 04     | 0x05     | 03       | nn |   | Switch error with low intensity (module nn)       |
|         | 04     | 0x05     | 04       | nn |   | Error with data pattern 1 (pattern 00)(module nn) |
|         | 04     | 0x05     | 05       | nn |   | Error with data pattern 2 (pattern FF)(module nn) |
|         | 04     | 0x05     | 06       | nn |   | Error with data pattern 3 (Pattern AA)(module nn) |
|         | 04     | 0x05     | 07       | nn |   | Switch error with high intensity (module nn)      |
|         | 04     | 0x05     | 09       | 00 |   | Continuous sending function active                |

"Error with high intensity" means that the ring already has an excessive attenuation during normal operation or that there may be a fracture point.

"Switch error with low intensity" means that the transwhere intensity of the module concerned cannot be reduced.

"Error with data pattern xx" indicates that the fibre-optic ring after the specified module has an excessive attenuation. It is nevertheless possible to operate the system, with the result that this malfunction can be remedied at a suitable point in time.

"Switch error with high intensity" means that the specified module can no longer be switched back to the full transwhere power.

### Count peripheral modules

The number of modules in the ring can be defined with this function.

| Channel | Length | Function | Argument |    |   | Comment                                  |
|---------|--------|----------|----------|----|---|--|
|         |        |          | 0        | 1  | 2 |  |
| Request | 02     | 0x06     |          |    |   |  |
| Reply   | 04     | 0x06     | 00       | nn |   | Count modules:<br>nn modules in the ring |
|         | 04     | 0x06     | 01       | 00 |   | Count modules:<br>Ring interrupted       |

### Test peripheral module addresses

By means of this function, a check is made as to whether the modules are still keeping to the addresses they received on initialization.

| Channel | Length | Function | Argument |    |   | Comment             |
|---------|--------|----------|----------|----|---|---------------------|
|         |        |          | 0        | 1  | 2 |                     |
| Request | 02     | 0x07     |          |    |   |                     |
| Reply   | 04     | 0x07     | 00       | 00 |   | Addresses correct   |
|         | 04     | 0x07     | 01       | nn |   | Error at address nn |

To guarantee maximum operating reliability, during normal operation this function can also be run cyclically in the background. In doing so, the function is activated by setting a bit in the GCB. In the event of an error, a message is sent to the PC via the GCB.

### Continuous sending

The continuous sending function only controls the 'Cycle' LEDs on the modules to determine how many modules are still connected to the transwhere output of the C1220. This function should only be activated if the 0x0a (Fracture point test) does not return a satisfactory result. On the software end, continuous sending can only be stopped by a RESET.

| Channel | Length | Function | Argument |   |   | Comment                                       |
|---------|--------|----------|----------|---|---|---|
|         |        |          | 0        | 1 | 2 |   |
| Request | 02     | 0x08     |          |   |   |   |
| Reply   | 03     | 0x08     | 01       |   |   | Continuous sending can be stopped by<br>RESET |

### Software-RESET

The C1220 can be reset by means of this function. Besides reinitialization of the fibre-optic ring, the controller and the dual ported RAM are also reinitialized. Completion of RESET is acknowledged by the code word (without Data Valid).

| Channel | Length | Function | Argument |    |   | Comment |
|---------|--------|----------|----------|----|---|---------|
|         |        |          | 0        | 1  | 2 |         |
| Request | 02     | 0x09     |          |    |   |         |
| Reply   | 04     | 0x02     | fe       | af |   |         |

### Fibre-optic fracture point test

A fracture point in the fibre-optic ring can be localized by this function. Depending on the result, the test specifies the number of boxes in the ring or the location of the fracture point.

| Channel | Length | Function | Argument |    |   | Comment  |
|---------|--------|----------|----------|----|---|--|
|         |        |          | 0        | 1  | 2 |  |
| Request | 02     | 0x0a     |          |    |   |  |
| Reply   | 04     | 0x0a     | 00       | nn |   | No fracture point,<br>nn modules in the ring                                 |
|         | 04     | 0x0a     | 01       | nn |   | Fracture point before nn th-module before<br>the receiver input of the C1220 |
|         | 04     | 0x0a     | 01       | ff |   | Fracture point cannot be located (fracture<br>point before receiver input)   |

If the fracture point should be specified as not being capable of location, it is probably located between the last module and the receive input of the C1220.

### Invalid function selection

If a function is requested via handshake channel 0 that is reserved or is not available, it is acknowledged with the function 0x0ff, which contains the invalid function number as Argument 0.

Example:

| Channel | Length | Function | Argument |   |   | Comment                          |
|---------|--------|----------|----------|---|---|----------------------------------|
|         |        |          | 0        | 1 | 2 |                                  |
| Request | 03     | 0x04     | 01       |   |   | Request function 4<br>(reserved) |
| Reply   | 03     | 0x0ff    | 04       |   |   |                                  |

## Configuration

A total of four functions is available for description of the configuration, of affiliation of the inputs or outputs in the Beckhoff Lightbus to the addresses in the DPRAM, and the affiliations of the modules to the processor groups. The configuration is also transwhereted via the handshake channels.

The management part of the communication functions must be reinitialized at the start of a new configuration.

Each of the maximum number of 8 communication functions can be optionally configured as CDL communication or as freely programmable communication.

A further function configures the interrupt channels for the address-independent interrupts.

### Reinitializing communication management

Both the CDLs and also the freely programmable communication functions consist of two parts, a data part and a management part. The management parts must be reset before new configurations are communicated. The management parts of all 8 communication functions are reset by activating the function 0ch.

| Channel | Length | Function | Argument |   |   | Comment |
|---------|--------|----------|----------|---|---|---------|
|         |        |          | 0        | 1 | 2 |         |
| Request | 02     | 0x0c     |          |   |   |         |
| Reply   | 03     | 0x0c     | 00       |   |   |         |

### CDL communication

A CDL is generated for each group of modules whose process image is to updated jointly. This CDL is composed of so-called descriptors. A descriptor describes a telegram for a module and is structured as follows:

| Bytes | Contents   |
|-------|--|
| 0,1   | I/O module address (1 - FE)  |
| 2,3   | Control Word :<br>0x0000: READ<br>0x0010: READ/WRITE<br>0x0030: RAM<br>0x00B0: BROADCAST |
| 4,5   | Pointer to byte for output in D0 of a message  |
| 6,7   | Pointer to byte for output in D1 of a message  |
| 8,9   | Pointer to byte for output in D2 of a message  |
| 10,11 | Pointer to byte for output in D3 of a message  |
| 12,13 | Pointer to byte for input in D0 of a message   |
| 14,15 | Pointer to byte for input in D1 of a message   |
| 16,17 | Pointer to byte for input in D2 of a message   |
| 18,19 | Pointer to byte for input in D3 of a message   |

Example of a descriptor:

Telegram to I/O module 1 :     D0 - D2     Outputs  
   D3            Input

The data for the output in D0 - D2 is fetched from the addresses 0x400, 0x302 and 0x210 in the DPRAM.

The data item for the input in D3 is stored at the address 0x30 in the DPRAM.

| Bytes | Contents   |
|-------|------------|
| 0,1   | 0x01, 0x00 |
| 2,3   | 0x10, 0x00 |
| 4,5   | 0x00, 0x04 |
| 6,7   | 0x02, 0x03 |
| 8,9   | 0x10, 0x02 |
| 10,11 | 0xff, 0xff |
| 12,13 | 0xff, 0xff |
| 14,15 | 0xff, 0xff |
| 16,17 | 0xff, 0xff |
| 18,19 | 0x30, 0x00 |

*Constants*

At the DPRAM adress offset 0xEF0 - 0xFEF the constants 0x00 - 0xFF can be found. To insert constants into the data bytes of the Lightbus telegrams, you just have to set the descriptor to the corresponding offset.

The above-mentioned CDLs are split into parts so they can be transferred via the handshake channel 0. In doing so, the information for a message must not be split. Transfer can be activated with the function 0x10.

| Channel | Length | Function | blank | Argument |    |       |     |        |
|---------|--------|----------|-------|----------|----|-------|-----|--------|
|         |        |          |       | 0        | 1  | 2     | ... | n      |
| Request | nn     | 0x10     | 00    | aa       | bb | db1,0 |     | dbn,19 |

| Channel | Length | Function | Argument |    |   | Comment   |
|---------|--------|----------|----------|----|---|---|
|         |        |          | 0        | 1  | 2 |   |
| Reply   | 04     | 0x10     | aa       | 00 |   | o.k.  |
|         | 04     | 0x10     | aa       | 01 |   | Error in CDL data<br>(e.g.: Pointer not in the DPRAM's data area) |
|         | 04     | 0x10     | aa       | 02 |   | CDL overflow  |
|         | 04     | 0x10     | aa       | 03 |   | Invalid descriptor length   |

where:

|               |  |
|---------------|--|
| <b>aa</b>     | 00 = start of a CDL transfer<br>01 = further descriptors of the same CDL<br>02 = last transfer of the same CDL |
| <b>bb</b>     | Process image No bb ( 1 ... 8)   |
| <b>db1,0</b>  | Descriptor 1, byte 0 of a CDL  |
| ...           | ...  |
| <b>dbn,19</b> | Descriptor n, byte 19 of a CDL (n = 2 ... 13)  |

The module address, the control byte and the pointers to the data bytes of a message are transferred in Intel notation (least significant byte at least significant address). If a pointer to a data byte in a message is not needed, a dummy pointer 0x0fff must be entered here.

The arguments 2 - n can be dropped when CDL transfer is concluded (Argument aa = 02).

## Freely programmable communication

With this mode of communication, telegrams are stored as from a previously defined address in the DPRAM and are combined in a process image. The input data is transferred to the PC system as from an address that is also defined beforehand.

With this function, the parameters necessary for initialization are transferred to the C1220.

| Channel | Length | Function | blank | Argument |    |        |        |
|---------|--------|----------|-------|----------|----|--------|--------|
|         |        |          |       | 0        | 1  | 2      | 3      |
| Request | 09     | 0x0b     | 00    | pan      | at | oa 0,1 | ia 0,1 |

| Channel | Length | Function | Argument 0 | Comment |
|---------|--------|----------|------------|---------|
| Reply   | 03     | 0x0b     | 00         | ok      |
|         | 03     | 0x0b     | 01         | Error   |

where:

|               |                             |
|---------------|-----------------------------|
| <b>pan</b>    | Process image number        |
| <b>at</b>     | Number of telegrams         |
| <b>oa 0,1</b> | Base address of output area |
| <b>ia 0,1</b> | Base address of input area  |

The base address of the output area defines the memory area in the DPRAM as from which the user-defined telegrams are stored. In doing so, only the address byte, the control byte and four data bytes are entered. The check byte is not entered. This entry is made internally by the controller.

As from the base address for the input area, the C1220 enters 0x00 for the address and control byte and the input data is stored.

Example:

Initialization of communication 3 as free communication with 2 telegrams. The base address for the output area is 0x400, and the base address for the input area is 0x210.

| Channel | Length | Function | blank | Argument |    |       |       |
|---------|--------|----------|-------|----------|----|-------|-------|
|         |        |          |       | 0        | 1  | 2     | 3     |
| Request | 09     | 0x0b     | 00    | 03       | 02 | 00,04 | 10,02 |

| Channel | Length | Function | Argument 0 | Comment |
|---------|--------|----------|------------|---------|
| Reply   | 03     | 0x0b     | 00         | ok      |

By means of this structure it is also possible to modify the module address and the control byte during the run time. One restriction here, however, is that this must not take place while communication is active.

### Cyclic communication

With the function 0x12, it is possible to trigger communication cyclically by the central module. In doing so, the otherwise necessary Handshake by way of the GCB is dropped.

| Channel | Length | Function | Argument 1 | Argument2 |
|---------|--------|----------|------------|-----------|
| Request | 04     | 0x12     | k          | pan       |

| Channel | Length | Function | Argument 0 | Comment |
|---------|--------|----------|------------|---------|
| Reply   | 03     | 0x12     | 00         | ok      |
|         | 03     | 0x12     | 01         | Error   |

where:

|     |   |
|-----|---|
| pan | Process image number  |
| k   | Status<br>0 = Communication passive<br>1 = Communication active |

In this mode of communication, however, only byte-oriented I/O functions should be executed because the timing behavior is no longer deterministic.

### Transmitting the interrupt mask

The module C1220 features 4 interrupt channels through which the address-independent interrupts are transferred to the PC. Transfer to the PC is realized via the GCB.

The address-independent interrupts can be generated by the peripheral modules. In doing so, they are inserted in the interrupt field of the control byte.

The function 0x0f is used to communicate to the module C1220 which interrupt channels are to be activated and which interrupt criteria are to lead to interrupt transmission to the PC.

Before the interrupts are activated, a read access must take place to the cell IRQ inputs in the General Control Block (see Chapter 3.5).

## String Communication

### General

String communication is used for packet oriented data exchange with peripheral modules. Usually, parameter data is exchanged with the modules (e.g. parameterisation of a BK2000 by register interface).

This type of communication also permits slave to slave communication, as well as communication between master and slave. The master card then functions simply as a relay station.

The following resources are required to carry out string communication:

- 2 CDLs for sending or receiving the strings.
- 2 buffers in DPRAM for string storage, the buffer size being parameterisable.

### String structure

A data string consists of a four-byte string header and a string data area. The header contains the necessary routing information, and the data area contains the user data itself. The entire string can have a maximum length of 255 bytes.

A string has the following structure:

| Offset | Description                                      |
|--------|--|
| 0x00   | Address of the sender (TX)                       |
| 0x01   | Address of the receiver (RX)                     |
| 0x02   | Channel / priority (only relevant to the BK2000) |
| 0x03   | String length                                    |
| 0x04   |  |
| ...    | String data                                      |
| 0xFF   |  |

### Initialisation of string communication

String communication is initialised via the handshake channel with function 0x14.

|                | Length | Function | Argument                  |  |                        |                    |
|----------------|--------|----------|---------------------------|--|------------------------|--------------------|
|                |        |          | 0                         | 1  | 2                      | 3                  |
| <b>Request</b> | 0x0A   | 0x14     | Init StringComm. (0x01)   | CDL no. string Trns  | CDL no. string receive | Max. string length |
| <b>Request</b> | 0x03   | 0x14     | Deinit StringComm. (0x00) | Deactivation of string communication also deactivates all the string slaves. |                        |                    |
| <b>Reply</b>   | 0x03   | 0x14     | 0x00                      | No error.  |                        |                    |
|                |        |          | 0x01                      | Wrong CDL number for string transmit CDL.                                    |                        |                    |
|                |        |          | 0x02                      | String transmit CDL already occupied.  |                        |                    |

|                |        |          | 0x04                      | String receive CDL already occupied.   |                        |                    |
|                |        |          | 0x05                      | Wrong transmit string base address.  |                        |                    |
|                |        |          | 0x06                      | Wrong receive string base address.   |                        |                    |

Continuation of the table

| Argument   |   |                              |   |
|--|---|------------------------------|---|
| 4  | 5 | 6                            | 7 |
| Offset string transmit buffer  |   | Offset string receive buffer |   |
| Deactivation of string communication also deactivates all the string slaves. |   |                              |   |
| No error.  |   |                              |   |
| Wrong CDL number for string transmit CDL.                                    |   |                              |   |
| String transmit CDL already occupied.  |   |                              |   |
| Wrong CDL number for string receive CDL.                                     |   |                              |   |
| String receive CDL already occupied.   |   |                              |   |
| Wrong transmit string base address.  |   |                              |   |
| Wrong receive string base address.   |   |                              |   |

### Registration of a string slave

Before string communication with a string slave is possible, it must be registered with the master card.

This is done by means of function 0x15.

|                | Length | Function | Argument |   |                       |   |
|----------------|--------|----------|----------|---|-----------------------|---|
|                |        |          | 0        | 1                                       | 2                     |   |
| <b>Request</b> | 0x0A   | 0x15     | SubFnc   | Physical slave address                  | Logical slave address |   |
| <b>Request</b> | 0x03   | 0x15     | 01       | Mn                                      | xy                    | Enter string slave without string reset.  |
|                |        |          | 02       | Mn                                      | Xy                    | Enter string slave with string reset.   |
|                |        |          | 03       | Mn                                      | Xy                    | Enter string slave without string reset. Transmission of the string without triggering an interrupt at the slave. |
|                |        |          | 04       | Mn                                      | xy                    | Enter string slave with string reset. Transmission of the string without triggering an interrupt at the slave.    |
|                |        |          | 00       | Mn                                      | xy                    | Deactivate string slave.  |
| <b>Reply</b>   | 0x03   | 0x15     | 0x00     | No error.                               |                       |   |
|                |        |          | 0x01     | Wrong slave address.                    |                       |   |
|                |        |          | 0x02     | Error during string reset at the slave. |                       |   |
|                |        |          | 0x03     | Optical fibre error.                    |                       |   |

Before communication with a slave is possible, a string reset must be successfully carried out. The string reset at a slave synchronises the handshake bits between master and slave. There are two ways to trigger a string reset:

- The reset is initiated by the master when the slave is registered.
- The reset is initiated at a later time by the slave (see also "Triggering a String Reset by the Slave").

A string slave is only addressed for string transmission by means of its logical slave address (although the logical address can be the same as the physical address).

### Structure of the buffer for string communication

| Transmit / receive buffer | Description   |
|---------------------------|---|
| 0x00.0                    | Active flag   |
| 0x00.1 - 0x00.7           | Error field<br>0x00: String transmitted without error.<br>0x04: Optical fibre error.<br>0x08: String slave not initialised.<br>0x10: String slave not yet ready for communication.<br>0x20: Timeout during string transmission.<br>0x40: String length error. |
| 0x01                      | Empty   |
| 0x02                      | Address of the sender (TX)  |
| 0x03                      | Address of the receiver (RX)  |
| 0x04                      | Channel / priority  |
| 0x05                      | String length   |
| 0x06 - 0xFF               | String data   |

#### Sending a string

To send a string to a string slave, the string data (header and user data) are placed in the C1220's transmit buffer. If the active flag is now set, the master card is induced to send the string. Once this has occurred, the master card now resets the active flag. If any error has occurred during the string transmission, this is indicated in the error field.

#### Receiving a string

If a string is received from a string slave, it is placed in the C1220's receive buffer, and the active flag is set. As long as a string that has been received has not been acknowledged by resetting the active flag, no further string will be fetched from a string slave.

#### Slave to slave string communication

Slave to slave communication (received string has RX not equal to "0") is processed entirely by the master card.

#### Register communication

String communication can be used to access the register interface of a bus coupler or of a terminal in a simple manner. To trigger register communication, channel 8 must simply be entered into the string header. In the string data area an additional header, 6 bytes large, is necessary.

| High Byte       | Low Byte        | I/O Address     |
|-----------------|-----------------|-----------------|
| Register data   |                 | 127             |
|                 |                 | --              |
|                 |                 | 5               |
| Number of words | Register (base) | 4               |
| R/W             | Table           | Terminal number |
| Message Ident   |                 | 2               |
| Size            | Priority        | 8               |
| RX_address      | TX_address      | 0               |

User data

Header for register communication

Header for string communication

## Process image control functions

The General Control Block serves to control and check updating of the individual process images. When a bit is set in the request mask the corresponding process image is updated and is reported as complete via the ready mask. After the complete message, the bit first has to be deleted from the request mask before communication can be restarted. It is possible to interrupt updating of a process image. If the request by a higher-priority update is triggered during an ongoing process updating in the request mask, the current operation is interrupted.

The corresponding bits are set in the error mask if errors in the fibre-optic ring are to be detected during normal operation.

### General Control Block

| Address | Contents          | Comment  |
|---------|-------------------|----------|
| 0x0FFF  | Request mask      |          |
| 0x0FFE  | IRQ outputs       |          |
| 0x0FFD  | Ready mask        |          |
| 0x0FFC  | IRQ inputs        |          |
| 0x0FFB  |                   | reserved |
| 0x0FFA  | Error-Mask        |          |
| 0x0FF9  | Control-Mask      |          |
| 0x0FF8  | -                 | reserved |
| 0x0FF7  | -                 | reserved |
| 0x0FF6  | -                 | reserved |
| 0x0FF5  | Firmware Revision |          |
| 0x0FF4  | Fimrware Release  |          |
| 0x0FF3  | -                 | reserved |
| 0x0FF2  | -                 | reserved |
| 0x0FF1  | -                 | reserved |
| 0x0FF0  | -                 | reserved |

### Request mask:

### Ready mask:

where: P7 => Process 08

...

P0 => Process 01

### Error mask:

E0 set = general fibre-optic error

E1 set = Address error in resident address check

E7 set = CPU error in the C1220

### IRQ output:

|  |  |  |  |  |  |  |  |
|--|--|--|--|--|--|--|--|
|  |  |  |  |  |  |  |  |
|--|--|--|--|--|--|--|--|

If the PC modifies this mask, it is inserted into the interrupt fields of the next telegrams. The nibble is inserted into the interrupt field until it is withdrawn again by the PC.

*IRQ inputs:*

|   |   |   |   |     |     |     |     |
|---|---|---|---|-----|-----|-----|-----|
| - | - | - | - | II3 | II2 | II1 | II0 |
|   |   |   |   |     |     |     |     |

If an address-independent interrupt is generated by an I/O module, it is transferred to the PC via this mask provided it is enabled by the interrupt mask.

Pending interrupts are buffered by the C1220, i.e. only ever one interrupt is transferred the PC via the GCB. Any other pending interrupt is not transferred until this one has been recognized by the PC.

*Control mask:*

|   |   |   |   |   |   |    |    |
|---|---|---|---|---|---|----|----|
| - | - | - | - | - | - | C1 | C0 |
|   |   |   |   |   |   |    |    |

Bit C0 can be used to allow the PC to switch off the resident address test, or to reactivate it. In order to be able to localise parity errors, the address check must be active.

C0 set : Address test active.

C1 reset : Address test active even with optical fibre errors.

C0 is set by default.

### C1220 I/O Error Counter

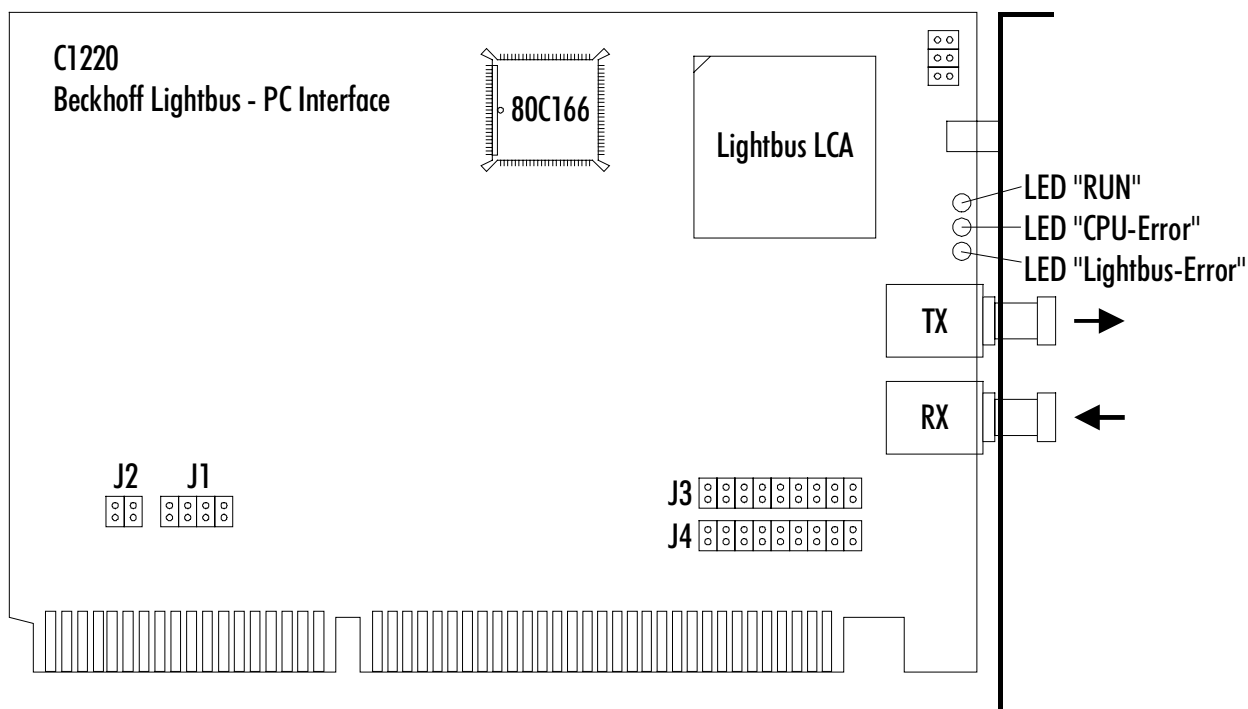

The C1220 has several counters to register I/O problems. The counters are stored in the DPRAM from offset 0xEE0, as 16-bit values. There is no overflow processing, and no erasure of the counters by the C1220.

The counter which registers the errors of the internal address check (0xEEA) is designed as an 8-bit counter, and does not increment the total error.

| DPRAM-Offset | Meaning  | Function  |
|--------------|--|---|
| <b>0xEE0</b> | Total error  | Delivers the number of error handling operations as the sum total of the individual error triggers (following)              |
| <b>0xEE2</b> | Error in receiver 1                                    | Address and/or control unequal to transmitted bytes   |
| <b>0xEE4</b> | Error in receiver 2                                    | Address and/or control unequal to transmitted bytes   |
| <b>0xEE6</b> | Timeout error  | Timeout in telegram reception   |
| <b>0xEE8</b> | Parity error   | Telegram received with CRC error  |
| -----        | -----  | -----   |
| <b>0xEEA</b> | Error in internal address check                        | When this counter is incremented an address check and count telegram with logically false content ( AD <> D3 ) is received. |
| <b>0xEEC</b> | Module address in case of internal address check error | If bit 1 is set in the C1220 error mask, this cell contains the module address of the box which caused the error.           |

# Technical Data

|                     |  |
|---------------------|--|
| Interface processor | Siemens SAB 80C166-S                             |
| Data connection     | Beckhoff Lightbus                                |
| Data transfer rate  | 2,5 MBaud, 32 Bits of user information in 25µsec |
| Supply voltage      | 5 V  |
| Current consumption | 800 mA   |
| Dimensions          | 161mm x 107mm                                    |

# Installation notes

## Jumper configuration

The C1220 interface card occupies one ISA bus slot on the PC's bus board. The fibre-optic ring is connected with two fibre optic connectors on the panel.

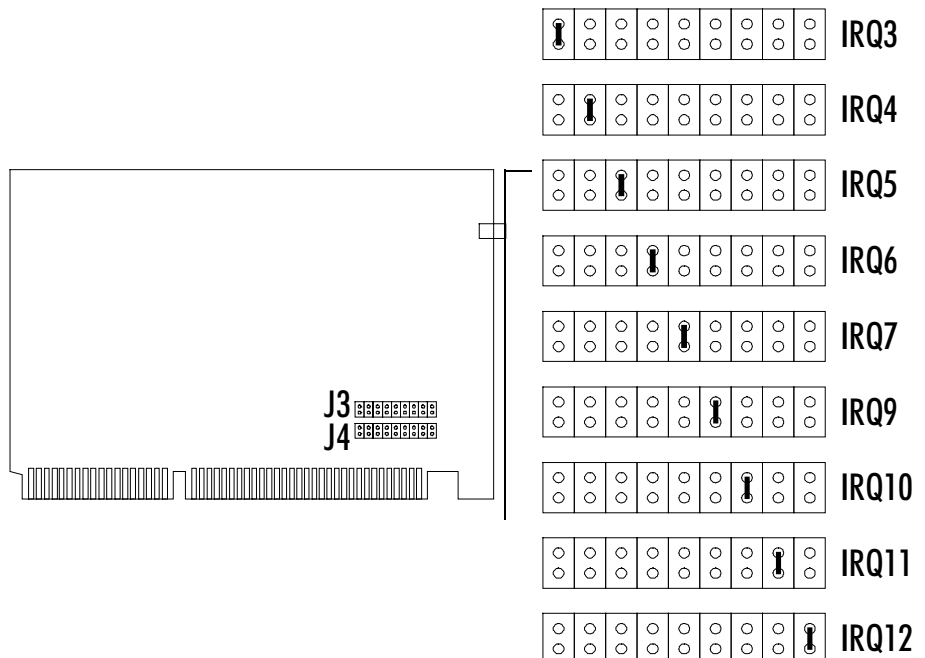

### Jumpers J1 and J2

The base address for the required 4 kbyte area of the PC address space is set by means of jumpers J2 and J1:

### Jumpers J3 and J4

The IRQ number of the Ready interrupt is defined by means of jumper J3. Jumper J4 defines the IRQ number of the fast interrupt inputs.

## Status display

There are 3 status display LEDs on the C1220.

### *"RUN" LED*

The 'RUN' LED indicates that the C1220 has initialized without errors and is ready for operation.

### *"CPU-Error" LED*

An irrecoverable hardware fault has occurred if only this LED lights up. If the 'RUN' LED also lights up, a program error has occurred which it might be possible to remedy by means of a hardware reset.

### *"Lightbus-Error" LED*

'LWL-FAIL' LED is activated if a defect occurs in the fibre optic ring during operation. The LED flashes if a general fibre-optic error has occurred. The LED is statically activated if the error has occurred during the resident address check. Updating of the process image is interrupted. The cause of the error can be determined by means of the available diagnostic functions.

## Installation in the PC

1. Switch off the PC and any external power supplies.
2. Insert the C1220 interface card in a 16-Bit ISA bus slot on the PC's bus board.

The C1220 does not require an external power supply. The card is powered directly by the PC. Therefore, when the PC is switched on, the C1220 also assumes operation. Before the C1220 can assume operation, however, the fibre-optic connections must be established and the jumpers of the C1220 must be configured correctly.
